## Description

The present invention relates to a ceramic-coated metal sheet which is decorative and of high weatherability and can be used as decorative material, interior material, construction material, automobile material and the like.

With development and maturation of techniques of electronics, a dry coating process such as physical vapor deposition or chemical vapor deposition has been practically utilized for the surface modification of metal materials. By dint of the progress of this technique, it has become possible to obtain ceramics-coated metal materials provided with such functions as weatherability, abrasion resistance, decorative property and far infrared characteristics, which could not be obtained by the conventional wet process represented by plating. However, this technique involves serious economical problems in that it is not suitable for mass production, the running cost is large and the apparatus is expensive. Therefore, the dry process cannot successfully replace the wet process on an industrial scale unless especially excellent performances or functions are attained.

In the field of decorative materials, a gold-color decorative coating of TiN is almost the only instance of successful industrialization while reflecting the recent trend toward high-quality products. For decorative coating, the color of which is utilizable, substances other than the above-mentioned TiN showing a gold color are hardly known. Accordingly, it is very difficult to provide a variety of colours, and only a few colors such as gold, black and grey are attainable at the present.

A variety of colors can be produced as so-called interference colors, namely by utilizing the interference of light (see, for example, Japanese Patent Application No. 54-66385 and Japanese Patent Application No. 54-85214). In the case of an interference color produced by an oxide or nitride of aluminum or silicon which are customarily used, the color changes greatly according to the viewing angle, and furthermore, since the range where the hue can be controlled by changing the thickness is narrow, the usefulness of the product as a decorative article is very low.

The present invention provides a coated metal sheet having an excellent decorative property and a high weatherability, in which by laminating a transparent ceramics having a high refractive index on a metal substrate or a colored ceramics layer formed on a metal sheet and greatly changing the hue of the metal sheet or colored ceramics, the variety of colors can be increased and the above-mentioned problem of the extreme change of the color according to the viewing angle can be solved to some extent.

In accordance with the present invention, there is provided a single ceramic layer-coated metal sheet having an excellent decorative property and a high weatherability, comprising a metal substrate and a transparent ceramic layer formed on the metal substrate by a dry coating process of physical vapor deposition or chemical vapor deposition, said transparent ceramics layer having a thickness of 0.05 to 5  $\mu\text{m}$  and a refractive index in the visible light region of at least 2.0 so as to exhibit a light interference effect giving a changed hue to said sheet.

Furthermore, in accordance with the present invention, there is provided a multiple ceramics layer-coated metal sheet having an excellent decorative property and a high weatherability, comprising a metal substrate, a colored ceramic layer as the first layer adjacent to the substrate, which is formed of at least one member selected from the group consisting of nitrides, carbides and carbonitrides of at least one element selected from the group consisting of Ti, Zr, Hf, Cr, Nb and Al, and is 0.1 to 1  $\mu\text{m}$  thick, and a transparent oxide ceramic layer as the second layer adjacent to the first layers which is formed by a dry process of physical vapor deposition or chemical vapor deposition and has a thickness of 0.05 to 5  $\mu\text{m}$  and a refractive index in the visible light region of at least 2.0 so as to exhibit a light interference effect giving a changed hue to said sheet.

US-A-4763601 and EP-A-0353060 disclose structures of a metal sheet with a layer which is non-transparent or of material of refractive index less than 2. GB-A-2083842 discloses an abrasion resistant layer on gold plating, the layer being too thin to give interference colour.

The excellent decorative property disclosed in the present invention can be attained only by coating a transparent ceramic layer having a high refractive index on a metal substrate or a colored ceramic layer formed as the first layer on a metal substrate, to greatly change the hue from the substance color of the metal substrate or colored ceramics.

The defect of the conventional technique, that is, the change of the color according to the viewing angle, can be eliminated to the maximum extent in the present invention, because the refraction angle of light advancing into the transparent oxide ceramics layer having a higher refractive index is large.

Moreover, since the transparent oxide ceramic layer has a high hardness, the metal sheet can be protected from external factors (for example, shock to the coating by gravel when the coated sheet is used for a construction material), and therefore, excellent weatherability and abrasion resistance can be realized.

As the metal substrate, there can be used stainless steel, titanium, copper, steel and aluminum, but substrates that can be used in the present invention are not limited to these metals. Especially when the coated sheet of the present invention is to be applied as a construction or automobile material, a ribbon-shaped or coil-shaped substrate having a large area (for example, 370 mm x 300 m) is preferably used.

5 In the case where a colored ceramic layer is formed as the first layer on the metal substrate, the colored ceramic layer is formed of at least one member selected from the group consisting of nitrides, carbides and carbonitrides of at least one element selected from the group consisting of Ti, Zr, Hf, Cr, Nb and Al. The thickness of the first layer is preferably 0.1 to 1  $\mu\text{m}$ , because if the thickness is smaller than 0.1  $\mu\text{m}$ , the degree of color obtained may not be sufficient, and since a sufficient color is already obtained at a  
10 thickness of up to 1  $\mu\text{m}$ , the thickness need not be increased beyond 1  $\mu\text{m}$ . Moreover, if the thickness of the first layer is too large, reduction of adhesion between the first layer and the metal substrate may occur. It is especially preferable that the thickness of the first layer is 0.2 to 0.5  $\mu\text{m}$ . If the thickness is 0.2  $\mu\text{m}$  or more, a sufficient substance color can be obtained, and in view of the cost, it is preferred that the thickness not be greater than 0.5  $\mu\text{m}$ .

15 The transparent oxide ceramic layer is formed of a transparent substance having a refractive index of at least 2.0. Preferably, the transparent ceramics layer is formed of at least one member selected from oxides of Ti, Zr, Hf, Th, V, Nb, Ta, W, Zn, Cd, Sn, Ba, Sb, Pb, Te and Ce, such as  $\text{TiO}_2$ ,  $\text{Nb}_2\text{O}_5$  and  $\text{ZrO}_2$ .

In the ceramics single layer-coated metal sheet of the present invention, the hue of the entire coated sheet is determined by the overlapping of the hue of the metal sheet as the substrate and the coloration by  
20 the interference effect of light in the transparent oxide ceramics.

In the ceramics multiple layer-coated metal sheet of the present invention, the hue of the entire coated sheet is determined by the hue of the colored ceramics layer as the first layer and the coloration by the interference effect of light in the transparent oxide ceramics layer.

In each case, the interference effect of light in the transparent ceramics layer causes a change of the  
25 hue, and the change of the hue by the interference effect is sharper as the refractive index of the substance of the transparent ceramic layer becomes higher.

The effect of the refractive index on the change of the hue will now be described in detail. The basic hue of the metal sheet of the present invention is determined according to the thickness of the topmost transparent ceramic layer. This is common to all transparent ceramic materials but the chroma, which is one  
30 element of the hue, that is, the sharpness, is greatly influenced by the refractive index.

In the transparent oxide ceramic coated sheet of the present invention, the majority of interference of reflected light occurs between the following two kinds of light among various reflected light originally incident on the surface of the coated metal sheet from air; namely, (1) light reflected from the surface of the transparent ceramic layer as the topmost layer and (2) light, not reflected from the topmost surface as light  
35 (1), but advancing through the transparent ceramic layer, reflected from the surface of the metal substrate or colored ceramic layer located just below the topmost layer, advancing through the transparent ceramics layer again and going out into the air. The closer the intensities of these two reflected lights (1) and (2) are to each other, the larger is the quantity of this interference.

In transparent oxide ceramic coated sheets, the intensity of reflected light (2) generally has an intensity  
40 several to ten or more times as high as the intensity of reflected light (1). Supposing that the refractive index of the transparent ceramic layer is  $n$  and the absorption coefficient is 0, the intensity (reflectance) of reflected light (1) is expressed by  $(n-1)^2/(n+1)^2$ , and becomes higher with higher  $n$ . For example, the reflectance of  $\text{SiO}_2$  (average refractive index 1.46) frequently used is about 3.5%, and that of  $\text{Nb}_2\text{O}_5$  - (average refractive index 2.25) included within the scope of the present invention is about 15%.

45 The influence of the refractive index of the transparent ceramics on the intensity of reflected light (2) is relatively small, and in each of the foregoing instances, the reflectance is scores of percent. Accordingly, in the case of conventional  $\text{SiO}_2$ , the intensity of reflected light (1) is much smaller than that of reflected light (2), and therefore, the interference is small. In contrast, in the case of  $\text{Nb}_2\text{O}_5$  used in the present invention, since the intensities of reflected lights (1) and (2) are brought close to each other, a large interference effect is caused. Generally, if the refractive index of the transparent oxide ceramics is at least 2.0, the intensity of  
50 reflected light (1) exceeds 10%, and a strong interference effect is caused.

As is seen from the foregoing description, if the refractive index of the transparent oxide ceramics layer becomes large, the extent of the light interference increases. In the system where the hue is manifested by the interference effect as in case of a ceramics-coated metal sheet, the larger is the interference quantity,  
55 the larger (sharper) the chroma of the hue. Accordingly, in a metal sheet with a transparent oxide ceramics film having a refractive index of at least 2.0 as the outermost layer, a sharp hue having a high chroma can be obtained.

The thickness of the transparent oxide ceramics layer is preferably 0.05 to 5  $\mu\text{m}$ . Since the basic hue is determined according to this thickness, a thickness showing a desired hue can be selected within this range. If the thickness is smaller than 0.05  $\mu\text{m}$ , the change of the hue may be small and the metal substrate-protecting effect insufficient. If the thickness exceeds 5  $\mu\text{m}$ , the change of hue may be small and the adhesion between the first and second layers reduced, so that good results may not be obtained.

As the dry coating process, ion plating or sputtering is preferable for forming the colored ceramics coating. If the number of interfaces increases as in the case of a multiple-layer coating, the adhesion becomes important, and a film having a good adhesion can be coated by ion plating. In order to improve the quality of the color of the colored ceramics, it is necessary to strictly control the stoichiometric ratio of the metal such as Ti, Zr, Hf, Cr, Nb or Al to nitrogen or carbon, and by sputtering, a film having the stoichiometric ratio can be easily coated.

Accordingly, when a ceramics-coated metal sheet having a colored ceramics layer is formed, there is preferably adopted a method in which in order to increase the adhesion to the metal substrate, the portion of the first layer close to the metal substrate is coated by ion plating, and in order to strictly control the stoichiometric ratio of the metal to nitrogen or carbon and obtain a high quality color, the portion of the first layer close to the second layer is coated by sputtering.

As a conventional method for coating a metal oxide, there can be mentioned a method in which a metal alkoxide or chelate is dissolved in an alcohol solution and thermal decomposition is carried out. According to this coating method utilizing thermal decomposition, the weatherability is improved to some extent, but the formed film has a porous structure characteristic of the process and the weatherability is not sufficient. Moreover, control of the film thickness is difficult, and the production of an interference color by adjusting the film thickness is impossible.

As other conventional methods there can be mentioned spraying method, roll coating method and spin coating method, but control of the film thickness is difficult in each of these methods. In view of the uniformity of the film thickness, the immersion draw-up method is preferable, but in this method, the thickness of the film is determined by the viscosity of the solution and the kind of the substrate, and control of the film thickness is difficult.

According to the present invention, appropriate dry coating processes are selected according to the kinds of films to be prepared as pointed out above, and a coated metal sheet that cannot be obtained by the conventional techniques can be provided.

For information of the transparent oxide ceramic coating, plasma CVD and sputtering are preferably used. The reason is that according to plasma CVD, a dense coating film can be formed and since scattering of light is not caused, an excellent interference transparent film can be obtained. Simultaneously, corrosion of the metal substrate by micro defects, for example, by pitting, can be prevented and the weatherability can be drastically improved. Furthermore, the above dry process is preferred since it is necessary that the refractive index of the transparent ceramics layer should be sufficiently increased and the stoichiometric ratio should be maintained between the metal element and oxygen.

As compared with transparent oxide ceramics film formed by plasma CVD, the improvement of the weatherability is poor in film formed by sputtering, but it is still possible to impart a high weatherability, and the stoichiometric ratio is more easily controlled in the case of sputtering. Moreover, sputtering is advantageous in that coating can be easily accomplished without using harmful substances such as silane, which is used as the starting gas in plasma CVD.

In the case where the colored ceramic is coated by ion plating or sputtering and the transparent oxide ceramics is coated by plasma CVD or sputtering, it is preferred that the first and second layers be continuously formed in one chamber. If vacuum is removed after formation of the first layer and the second layer is formed after the sample is taken out in the open air, gas components in the air, especially oxygen gas and water, are left between the first and second layers, and hence the interface between the first and second layers is broken and the adhesion is reduced. Furthermore, if the first and second layers are formed in separate chambers, since the temperature of the substrate is elevated and dropped, internal stress is produced in the film and increase and reduction of the internal stress are repeated. Accordingly, cracks are readily formed in the coating layer and reduction of the adhesion between the metal substrate and the first layer is caused.

#### Example 1

By using continuous coating equipment in which a cleaning mechanism, an ion plating apparatus, a sputtering apparatus and a plasma CVD apparatus were arranged in series between a coil unwinding mechanism and a coil winding mechanism, TiN having a thickness of 0.6  $\mu\text{m}$  as the first layer and  $\text{Nb}_2\text{O}_5$

having a thickness of 0.121  $\mu\text{m}$  as the second layer were continuously laminated by ion plating and sputtering, respectively, on coiled ferrite type stainless steel having a width of 370 mm, a length of 300 m and a thickness of 0.5 mm.

When the refractive index of the second layer was measured by ellipsometry and varied angle reflectometry, it was found that the average refractive index was 2.25. Prior to the laminating operation, the substrate was subjected to ion bombardment with argon gas as the undercoat treatment in a cleaning room.

The hue of the two-layer film was a much sharper yellow color different from the gold color of TiN. The film thickness of  $\text{Nb}_2\text{O}_5$  was changed in the above-mentioned combination while fixing the TiN film thickness to 0.6  $\mu\text{m}$ . The observed difference of the hue is summarized in Table 1. The hue was measured and calculated according to the L\*a\*b\* color coordinate system by using a commercially available colorimeter.

For comparison, the change of the hue observed in the  $\text{SiO}_2/\text{TiN}$  two-layer film is shown in Table 1. The refractive index of  $\text{SiO}_2$  in the visible region was about 1.46. When this comparative sample is compared with the example comprising  $\text{Nb}_2\text{O}_5$ , it is seen that the change of the hue is small with that of TiN being as the center in the comparative sample.

When a single layer of TiN was formed on the stainless steel, in the weatherability test, the weatherability was almost the same as the weatherability of the surface of the stainless steel. In contrast, in the case where  $\text{Nb}_2\text{O}_5$  was coated on TiN in the above-mentioned manner, the rust-preventive life was more than 4 times as long as that of the surface of the stainless steel.

When the surface hardness was measured by a micro hardness meter comprising a triangular indenter for evaluating the scratch resistance of the surface, it was found that the surface hardness of the sample obtained in this example was 1000  $\text{kg/mm}^2$  while the surface hardness of the uncoated substrate was 270  $\text{kg/mm}^2$ , and it was confirmed that the hardness was considerably increased.

## Example 2

By using continuous coating equipment in which a cleaning mechanism, an ion plating apparatus, a sputtering apparatus and a plasma CVD apparatus were arranged in series between a coil unwinding mechanism and a coil winding mechanism, TiN having a thickness of 0.6  $\mu\text{m}$  as the first layer and  $\text{TiO}_2$  having a thickness of 0.091  $\mu\text{m}$  as the second layer were continuously laminated by ion plating and sputtering, respectively, on coiled ferrite type stainless steel having a width of 370 mm, a length of 300 m and a thickness of 0.5 mm.

When the refractive index of the second layer was measured by ellipsometry and varied angle reflectometry, it was found that the average refractive index was 2.90. Prior to the laminating operation, the substrate was subjected to ion bombardment with argon gas as the undercoat treatment in a cleaning room.

The hue of the two-layer film was a much sharper yellow color different from the gold color of TiN. The film thickness of  $\text{TiO}_2$  was changed in the above-mentioned combination while fixing the TiN film thickness to 0.6  $\mu\text{m}$ . The observed difference of the hue is summarized in Table 2. The hue was measured and calculated according to the L\*a\*b\* color coordinate system by using a commercially available colorimeter.

When a single layer of TiN was formed on the stainless steel, in the weatherability test, the weatherability was almost the same as the weatherability of the surface of the stainless steel. In contrast, in the case where  $\text{TiO}_2$  was coated on TiN in the above-mentioned manner, the rust-preventive life as more than 5 times as long as that of the surface of the stainless steel.

When the surface hardness was measured by a micro hardness meter comprising a triangular indenter for evaluating the scratch resistance of the surface, it was found that the surface hardness of the sample obtained in this example was 1200  $\text{kg/mm}^2$  while the surface hardness of the uncoated substrate was 270  $\text{kg/mm}^2$ , and it was confirmed that the hardness was considerably increased.

## Example 3

TiC having a thickness of 0.5  $\mu\text{m}$  as the first layer and  $\text{TiO}_2$  having a thickness of 0.2  $\mu\text{m}$  as the second layer were laminated by ion plating and sputtering, respectively, on a coiled ferrite type stainless steel having a thickness of 0.5 mm. The obtained hue was a gentle dark green color. The film thickness of  $\text{TiO}_2$  was changed while fixing the film thickness of TiC to 0.5  $\mu\text{m}$  in the above-mentioned combination, and the change of the hue was examined. Also in this example, a delicate change of the color was clearly manifested.

In the case where a single layer of TiC was formed, in the weatherability test, the weatherability was extremely poor and the rust-preventive life was about 1/2 of that of the stainless steel surface. If  $\text{TiO}_2$  was

further coated on TiC, the rust-preventive life was improved and the weatherability was comparable to that of the surface of the stainless steel.

#### Example 4

5

HfN having a thickness of 0.8  $\mu\text{m}$  as the first layer and  $\text{ZrO}_2$  having a thickness of 0.1  $\mu\text{m}$  as the second layer were continuously laminated by ion plating or sputtering, respectively, on a coiled ferrite type stainless steel having a thickness of 0.5 mm. When the refractive index of the second layer was measured by ellipsometry and varied angle reflectometry, it was found that the average refractive index was 2.75. The hue of the obtained two-layer film was a much sharper yellow color different from the gold color of HfN.

10

In the above-mentioned combination, the thickness of  $\text{ZrO}_2$  was changed while fixing the thickness of HfN to 0.8  $\mu\text{m}$ . The observed difference of the color is summarized in Table 3. The hue was measured and calculated according to the L\*a\*b\* color coordinate system by using a commercially available colorimeter. As is seen from Table 3, the tendency of the change of the color in the combination of  $\text{ZrO}_2$ /HfN was substantially the same as the tendency observed in the combination of  $\text{ZrO}_2$ /HfN.

## Claims

1. A ceramic single layer-coated metal sheet which comprises a metal sheet substrate and a transparent oxide ceramic layer formed on the metal sheet substrate by a dry process selected from physical vapor deposition and chemical vapor deposition, said transparent ceramic layer having a thickness of 0.05 to 5  $\mu\text{m}$  and a refractive index in the visible light region of at least 2.0 so as to exhibit a light interference effect giving a changed hue to said sheet.
2. A ceramic multiple layer-coated metal sheet which comprises a metal sheet substrate, a colored ceramic first layer 0.1 to 1  $\mu\text{m}$  thick on and adjacent to the substrate and formed of at least one material selected from the nitrides, carbides and carbonitrides of Ti, Zr, Hf, Cr, Nb and Al, and a transparent oxide ceramic second layer on and adjacent to the first layer and formed by a dry process selected from physical vapor deposition and chemical vapor deposition, the second layer having a thickness of 0.05 to 5  $\mu\text{m}$  and a refractive index in the visible light region of at least 2.0 so as to exhibit a light interference effect giving a changed hue to said sheet.
3. A sheet according to claim 2 wherein said first layer is a layer deposited by ion plating and said second layer is a layer deposited by sputtering.
4. A sheet according to any of claims 1 to 3 wherein said metal sheet is a ribbon rolled in the form of a coil.
5. A sheet according to any preceding claim wherein said transparent ceramic layer is made of at least one material selected from the oxides of Ti, Zr, Hf, Th, V, Nb, Ta, W, Zn, Cd, Sn, Ba, Sb, Pb, Te and Ce.
6. A sheet according to claim 5 wherein said transparent ceramic layer is made of material selected from  $\text{TiO}_2$ ,  $\text{Nb}_2\text{O}_5$  and  $\text{ZrO}_2$ .

## Patentansprüche

1. Mit einer einzelnen Keramikschrift überzogenes Metallblech, das ein Metallblechsubstrat und eine transparente Oxidkeramikschrift umfaßt, die auf dem Metallblechsubstrat durch ein Trockenverfahren gebildet wurde, das aus physikalischem Bedampfen und chemischem Bedampfen ausgewählt ist, wobei die transparente Keramikschrift eine Dicke von 0,05 bis 5  $\mu\text{m}$  und einen Brechungsindex im Bereich des sichtbaren Lichtes von mindestens 2,0 aufweist, so daß ein Lichtinterferenzeffekt auftritt, der dem Blech einen veränderten Farbton verleiht.
2. Mit mehreren Keramikschriften überzogenes Metallblech, das ein Metallblechsubstrat, eine gefärbte erste Keramikschrift mit einer Dicke von 0,1 bis 1  $\mu\text{m}$  auf dem Substrat und daran angrenzend und aus mindestens einem Material gebildet, das aus Nitriden, Carbiden und Carbonitriden von Ti, Zr, Hf, Cr, Nb und Al ausgewählt ist, und eine zweite transparente Oxidkeramikschrift auf der ersten Schicht und daran angrenzend und durch ein Trockenverfahren gebildet, das aus physikalischem Bedampfen und chemischem Bedampfen ausgewählt ist, umfaßt, wobei die zweite Schicht eine Dicke von 0,05 bis 5  $\mu\text{m}$  und einen Brechungsindex im Bereich des sichtbaren Lichtes von mindestens 2,0 aufweist, so daß ein Lichtinterferenzeffekt auftritt, der dem Blech einen veränderten Farbton verleiht.
3. Blech nach Anspruch 2, wobei die erste Schicht eine durch Ionenplattieren aufgebrachte Schicht und die zweite Schicht eine durch Zerstäuben aufgebrachte Schicht ist.
4. Blech nach einem der Ansprüche 1 bis 3, wobei das Metallblech ein gewalztes Band in Form einer Rolle ist.
5. Blech nach einem der vorstehenden Ansprüche, wobei die transparente Keramikschrift aus mindestens einem Material besteht, das aus Oxiden von Ti, Zr, Hf, Th, V, Nb, Ta, W, Zn, Cd, Sn, Ba, Sb, Pb, Te und Ce ausgewählt ist.

6. Blech nach Anspruch 5, wobei die transparente Keramikschrift aus einem Material besteht, das aus  $\text{TiO}_2$ ,  $\text{Nb}_2\text{O}_5$  oder  $\text{ZrO}_2$  ausgewählt ist.

# Revendications

- 5 1. Feuille métallique revêtue d'une seule couche céramique, qui comprend un substrat en feuille métallique et une couche céramique d'oxyde transparente formée sur le substrat en feuille métallique par un procédé à sec choisi parmi le dépôt physique à la vapeur et le dépôt chimique à la vapeur, ladite couche céramique transparente ayant une épaisseur de 0,05 à 5  $\mu\text{m}$  et un indice de réfraction  
10 dans la plage de lumière visible d'au moins 2,0, de manière à présenter un effet d'interférence de lumière conférant une teinte modifiée à ladite feuille.
2. Feuille métallique revêtue de couches céramiques multiples, qui comprend un substrat en feuille métallique, une première couche céramique colorée d'une épaisseur de 0,1 à 1  $\mu\text{m}$  sur et adjacente au  
15 substrat et formée d'au moins un matériau choisi parmi les nitrures, carbures et carbonitrures de Ti, Zr, Hf, Cr, Nb et Al, et une seconde couche de céramique d'oxyde transparente sur et adjacente à la première couche et formée par un procédé à sec choisi parmi le dépôt physique à la vapeur et le dépôt chimique à la vapeur, la seconde couche ayant une épaisseur de 0,05 à 5  $\mu\text{m}$  et un indice de réfraction dans la plage de lumière visible d'au moins 2,0, de manière à présenter un effet d'interférer-  
20 ce de lumière conférant une teinte modifiée à ladite feuille.
3. Feuille suivant la revendication 2, dans laquelle ladite première couche est une couche déposée par placage ionique et ladite seconde couche est une couche déposée par dépôt par pulvérisation.
- 25 4. Feuille suivant l'une ou l'autre des revendications 1 à 3, dans laquelle ladite feuille métallique est un ruban enroulé sous forme de rouleau.
5. Feuille suivant l'une ou l'autre des revendications précédentes, dans laquelle ladite couche céramique transparente est réalisée en au moins un matériau choisi parmi les oxydes de Ti, Zr, Hf, Th, V, Nb, Ta, W, Zn, Cd, Sn, Ba, Sb, Pb, Te et Ce.  
30
6. Feuille suivant la revendication 5, dans laquelle ladite couche céramique transparente est réalisée en un matériau choisi parmi  $\text{TiO}_2$ ,  $\text{Nb}_2\text{O}_5$  et  $\text{ZrO}_2$ .
